# **Reach Algorithm**

#### Pruning leads to amazing speedup.

Andrew V. Goldberg (MSR-SVC)

Highway Dimension

4/5/10 11/37

### Algorithm intuition

• Reach pruning (RE): Local intersections far from origin/destination can be ignored.

### Algorithm intuition

- Reach pruning (RE): Local intersections far from origin/destination can be ignored.
- Highway/contraction hierarchies (CH): Shortest path goes from local roads to local highways to global highways to local highways to local roads.

### Algorithm intuition

- Reach pruning (RE): Local intersections far from origin/destination can be ignored.
- Highway/contraction hierarchies (CH): Shortest path goes from local roads to local highways to global highways to local highways to local roads.
- Transit nodes (TN): For any region, a small number of "toll booths" covers all sufficiently long optimal in/out paths.

### Algorithm intuition

- Reach pruning (RE): Local intersections far from origin/destination can be ignored.
- Highway/contraction hierarchies (CH): Shortest path goes from local roads to local highways to global highways to local highways to local roads.
- Transit nodes (TN): For any region, a small number of "toll booths" covers all sufficiently long optimal in/out paths.

These intuitive ideas can be mathematically formalized and lead to provably correct algorithms which work very well on road networks.

## **Reach Fundamentals**

#### [Gutman 04; Goldberg et al. 06]

Preprocessing computes intersection locality.

Query uses locality to prune search.

# **Reach Fundamentals**

### [Gutman 04; Goldberg et al. 06]

Preprocessing computes intersection locality.

Query uses locality to prune search.

A D M A A A M M

### Definition of reach

• Consider a vertex v that splits a path P into  $P_1$  and  $P_2$ .  $r_P(v) = \min(\ell(P_1), \ell(P_2)).$ 

# **Reach Fundamentals**

### [Gutman 04; Goldberg et al. 06]

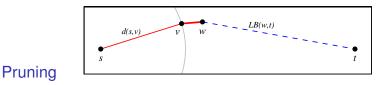

Preprocessing computes intersection locality.

Query uses locality to prune search.

### Definition of reach

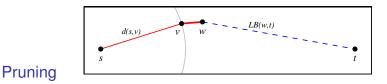

- Consider a vertex v that splits a path P into  $P_1$  and  $P_2$ .  $r_P(v) = \min(\ell(P_1), \ell(P_2)).$
- $r(v) = \max_P(r_P(v))$  over all shortest paths *P* through *v*.

# Pruning Search Using Reach

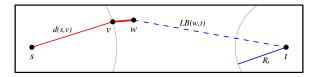

If  $r(w) < \min(d(v) + \ell(v, w), LB(w, t))$  then prune w.

# Pruning Search Using Reach

If  $r(w) < \min(d(v) + \ell(v, w), LB(w, t))$  then prune w.

### Lower bounds for nothing

Bidirectional search gives implicit bounds ( $R_t$  below).

Andrew V. Goldberg (MSR-SVC)

# **RE Algorithm**

### **RE Query**

- Bidirectional Dijkstra's algorithm with pruning based on reaches.
- A small change to Dijkstra's algorithm.

# **RE Algorithm**

### **RE Query**

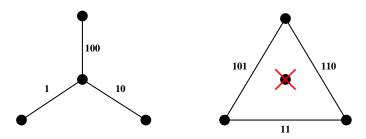

- Bidirectional Dijkstra's algorithm with pruning based on reaches.
- A small change to Dijkstra's algorithm.

### Remarks

- O(nm) perprocessing impractical on large graphs.
- Fast heuristic preprocessing computes reach upper bounds.
- Shortcuts speed up both preprocessing and query.
- CH algorithm shows that shortcuts are crucial.

# Shortcut Operation

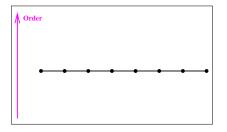

[Sanders & Schultes 05] The key operation for Contraction Hierarchies algorithm

A shortcut arc can be omitted if redundant (alternative path exists).

# **TN Preprocessing**

## [Bast et al. 06]

## Basic concepts

- Divide a map into regions (a few thousand).
- For each region, optimal paths to far away places pass through one of a small number of access nodes ( $\approx 10$  on the average).
- The union of access nodes is the set of transit nodes ( $\approx 10\,000$ ).

# **TN Preprocessing**

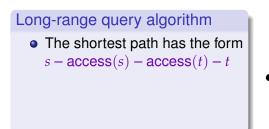

## [Bast et al. 06]

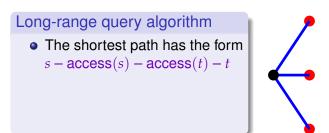

## Basic concepts

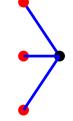

- Divide a map into regions (a few thousand).
- For each region, optimal paths to far away places pass through one of a small number of access nodes ( $\approx 10$  on the average).
- The union of access nodes is the set of transit nodes ( $\approx 10\,000$ ).

- Find access nodes for every region.
- Connect each vertex to its access nodes.
- Compute all pairs of shortest paths between transit nodes.

# Long-range query algorithm The shortest path has the form s - access(s) - access(t) - t

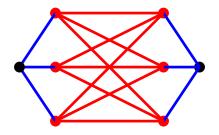

Andrew V. Goldberg (MSR-SVC)

4/5/10 20 / 37

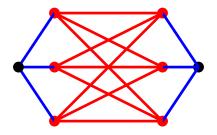

## Long-range query algorithm

The shortest path has the form
s - access(s) - access(t) - t

## Long-range query algorithm

- The shortest path has the form s - access(s) - access(t) - t
- Table look-up for the (access(s), access(t)) node pairs.

## Remarks

- Very fast:  $10 \times 10$  table look-ups per long-range query.
- Local queries: another method or hierarchical approach.

(4) (5) (4) (5)

# **Theoretical Results**

## Practice

- Intuitive and practical algorithms, but...
- Why do they work well on road networks?
- What is a road network (formally)?

# **Theoretical Results**

## Practice

- Intuitive and practical algorithms, but...
- Why do they work well on road networks?
- What is a road network (formally)?

Theory [Abraham, Fiat, Goldberg & Werneck 10]

- Define highway dimension (HD).
- Good time bounds for the three algorithms assuming HD is small.
- Analysis highlights algorithm similarities.
- Generative model of small HD networks (road network formation).

In the spirit of the small world model [Milgram 67, Kleinberg 99].

Andrew V. Goldberg (MSR-SVC)

**Highway Dimension** 

# **Definitions and Remarks**

## Definitions and assumptions

- Constant maximum degree.
- $B_{v,r}$  denotes the set of vertices within distance r from v.
- |P| denotes the length of P.
- h denotes highway dimension.
- k denotes either h or O(h log n) (exponential or poly-time preprocessing).
- Network diameter *D*.

## Definitions and assumptions

- Constant maximum degree.
- $B_{v,r}$  denotes the set of vertices within distance r from v.
- |P| denotes the length of P.
- h denotes highway dimension.
- *k* denotes either *h* or *O*(*h* log *n*) (exponential or poly-time preprocessing).
- Network diameter D.

## Remarks

- HD definition motivated by Transit Nodes.
- Preprocessing based on Contraction Hierarchies ideas.
- Analysis based on Reach ideas.

# Highway Dimension Motivation

Andrew

For a region, there is a small set of nodes such that all sufficiently long shortest paths out of the region pass a node in the set.

# Highway vs. Doubling Dimension

## Definition

A metric space has a doubling dimension  $\alpha$  if every ball of radius *r* can be covered by  $2^{\alpha}$  balls of radius r/2.

# Highway vs. Doubling Dimension

## Definition

A metric space has a doubling dimension  $\alpha$  if every ball of radius *r* can be covered by  $2^{\alpha}$  balls of radius r/2.

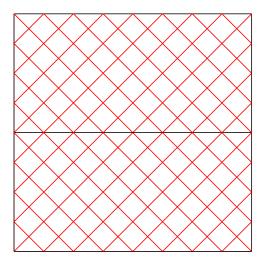

#### Line: Small HD

A line has HD 7 and doubling dimension 1.

| Andrew | V. | Goldberg | (MSR-SVC) |
|--------|----|----------|-----------|
|--------|----|----------|-----------|

## Grid: High HD

A grid has HD  $\Theta(\sqrt{n})$  and the doubling dimension 2.

# Shortest Path Covers

All SPs in a range can be covered by a sparse set.

(r,k) Shortest path cover ((r,k)-SPC): A set *C* such that

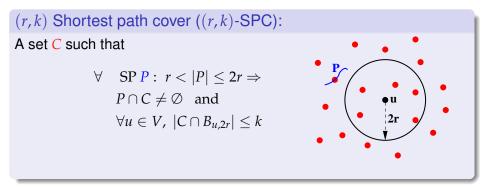

$$\forall \quad \text{SP } P: \ r < |P| \le 2r \Rightarrow$$
$$P \cap C \neq \emptyset \quad \text{and}$$
$$\forall u \in V, \ |C \cap B_{u,2r}| \le k$$

< ∃ ►

# Shortest Path Covers

All SPs in a range can be covered by a sparse set.

Can use constants different from 4 and 2, but the constants are related.

### Theorem

If *G* has highway dimension *h*, then  $\forall r \exists an (r,h)$ -SPC.

**Proof idea:** Show that  $S^*$ , the smallest set that covers all shortest paths  $P: r < |P| \le 2r$ , is an (r, h)-SPC.

4 3 5 4 3

### Theorem

If *G* has highway dimension *h*, then  $\forall r \exists an (r,h)$ -SPC.

**Proof idea:** Show that  $S^*$ , the smallest set that covers all shortest paths P:  $r < |P| \le 2r$ , is an (r, h)-SPC.

Finding S\* is NP-hard. Efficient construction?

## Theorem

If *G* has highway dimension *h*, then  $\forall r \exists an (r,h)$ -SPC.

**Proof idea:** Show that  $S^*$ , the smallest set that covers all shortest paths  $P: r < |P| \le 2r$ , is an (r, h)-SPC.

Finding  $S^*$  is NP-hard. Efficient construction?

### Theorem

If *G* has highway dimension *h*, then for any *r* we can construct, in polynomial time, an  $(r, O(h \log n))$ -SPC.

**Proof idea:** Use the greedy set-cover algorithm to get an  $O(\log n)$  approximation of  $S^*$ .

# **Generic Preprocessing**

- Let  $S_0 = V$ . For  $1 \le i \le \log D$  build  $(2^i, k)$ -SPC covers  $S_i$ .
- Let  $L_i = S_i \bigcup_{i=1}^{\log D} S_j$  (vertex partitioning into layers).
- Order vertices so that L<sub>i</sub> comes before L<sub>i+1</sub>; ordering inside layers is arbitrary.
- Do shortcutting in this order to get  $E^+$ .

### Preprocessing algorithm

- Let  $S_0 = V$ . For  $1 \le i \le \log D$  build  $(2^i, k)$ -SPC covers  $S_i$ .
- Let  $L_i = S_i \bigcup_{i+1}^{\log D} S_j$  (vertex partitioning into layers).
- Order vertices so that L<sub>i</sub> comes before L<sub>i+1</sub>; ordering inside layers is arbitrary.
- Do shortcutting in this order to get *E*<sup>+</sup>.

### Running time

Preprocessing is exponential (k = h) or polynomial  $(k = O(h \log n)))$ .

#### Lemma

For  $v \in L_i$ ,  $j \ge i$ , the number of  $(v, w) \in E^+$  with  $w \in L_j$  is at most k.

**Proof.** (v, w) corresponds to *P* with internal vertices less than v, w. Thus  $w \in B_{v,2\cdot 2^i}$ . The SPC definition implies the lemma.

#### Lemma

For  $v \in L_i$ ,  $j \ge i$ , the number of  $(v, w) \in E^+$  with  $w \in L_j$  is at most k.

**Proof.** (v, w) corresponds to *P* with internal vertices less than v, w. Thus  $w \in B_{v,2\cdot 2^i}$ . The SPC definition implies the lemma.

#### Theorem

In  $(V, E \cup E^+)$ , vertex degrees are bounded by  $O(k \log D)$  and  $|E \cup E^+| = O(nk \log D)$ 

#### Lemma

For  $v \in L_i$ ,  $j \ge i$ , the number of  $(v, w) \in E^+$  with  $w \in L_j$  is at most k.

**Proof.** (v, w) corresponds to *P* with internal vertices less than v, w. Thus  $w \in B_{v,2\cdot 2^i}$ . The SPC definition implies the lemma.

#### Theorem

In  $(V, E \cup E^+)$ , vertex degrees are bounded by  $O(k \log D)$  and  $|E \cup E^+| = O(nk \log D)$ 

### Things are better than the worst case in practice.

# **RE** Preprocessing

### Remarks

- Reach bounds are in the graph with shortcuts.
- Break ties based on hop count (prefer shortcuts).

#### Lemma

If  $v \in L_i$  then reach $(v) \leq 2 \cdot 2^i$ .

**Proof:** Suppose the reach is greater. Then there is a shortest path *P* that *v* divides into  $P_1$  and  $P_2$  with  $|P_1|$ ,  $|P_2| > 2 \cdot 2^i$ . Both  $P_1$  and  $P_2$  contain vertices in  $L_j$  with j > i, so there is a shortcut from  $P_1$  to  $P_2$ . But then *P* is not a shortest path.

Additional work is linear.

A THE A THE A

# **Query Time Bounds**

#### Theorem

RE query takes  $O((k \log D)^2)$  time.

**Proof:** Consider a forward search from *s*. In  $B_{s,2\cdot2^i}$ , the search scans only vertices of  $L_i$  in  $B_{s,2\cdot2^i}$ . Thus  $O(k \log D)$  scans.

< 回 > < 回 > < 回 > -

# **Query Time Bounds**

#### Theorem

RE query takes  $O((k \log D)^2)$  time.

**Proof:** Consider a forward search from *s*. In  $B_{s,2\cdot2^i}$ , the search scans only vertices of  $L_i$  in  $B_{s,2\cdot2^i}$ . Thus  $O(k \log D)$  scans.

## Remarks

- Shortest path can be extracted in time linear in the number of its arcs.
- Similar analysis for CH yields the same bound.
- Also develop a faster version of TN:  $O(k \log D)$  query.

# **Network Formation**

Natural networks with constant highway dimension?

Attempt to model road networks

- Build on the Earth surface (low doubling dimension).
- Build in decentralized and incremental manner.
- Highways are faster than local roads.

Capture some, but not all, real-life properties.

# **Network Formation**

Natural networks with constant highway dimension?

Attempt to model road networks

- Build on the Earth surface (low doubling dimension).
- Build in decentralized and incremental manner.
- Highways are faster than local roads.

Capture some, but not all, real-life properties.

## Setting

- Metric space (M, dist), doubling dim.  $\log \alpha$ , diameter *D*.
- Speedup parameter  $\delta \in (0, 1)$ .
- Edge  $\{v, w\}$  has length dist(v, w) and transit time  $\tau(v, w) = dist^{1-\delta}(v, w)$ . (Long roads are fast.)
- On-line network formation, adversarial vertex placement.

## Network Formation (cont.)

In the spirit of dynamic spanners [Gottlieb & Roditty 08].

- Adversary adds vertices, we connect them.
- Intuition: connect a new village to all nearby villages and to the closest town.
- Formally: maintain covers  $C_i$  for  $0 \le i \le \log D$ .  $C_0 = V, C_{i+1} \subseteq C_i$ , vertices in  $C_i$  are at least  $2^i$  apart.
- When adding a new vertex *v*, add *v* to *C*<sub>0</sub>,...,*C*<sub>*i*</sub> for appropriate *i*. (The first vertex added to all *C*'s.)
- For  $0 \le j \le i$ , connect v to  $C_j \cap B_{v,6 \cdot 2^j}$ .
- If  $i < \log D$ , connect v to the closest element of  $C_{i+1}$ .

### Theorem

The network has highway dimension of  $\alpha^{O(1)}$ .

## Summary

- Intuitive and practical routing algorithms.
- Efficient implementations.
- Used in practice.
- Theoretical understanding and justification.
- Further research, e.g., improved bounds or algorithms for other problems assuming small HD (TSP, vehicle routing, etc.).
- Static problem solved, dynamic active research area.
  - Real time traffic.
  - Historical data.
  - Combination (prediction).
